	(a) The momentary deflection is due to the transient current flowing through the circuit when the capacitor is getting charged.The deflection would be zero when the capacitor gets fully charged.	1/2	
	(b) We consider the charging of a capacitor when it is being charged by connecting it to a dc source.		
	i(t)		
	In Ampere's circuital law, namely $B(2\pi r) = \mu_0 i$ We have i as non zero for surface (a) but zero for surface (c)		
	Hence there is a contradiction in the value of B; calculated one way we have a	1/

	To remove this contradiction the concept of displacement current	1/2	
	$(i_d = \varepsilon_0 \frac{d\phi_E}{dt} = i)$ was introduced	1/2

	This form gives consistent results for values of B irrespective of which surface is used to calculate it.		3

		1/2	
	For the magnetic field at a point S inside a toroid we have		
	$B(2 \pi r) = \mu_{\circ} NI$ $B = \mu_{\circ} \frac{NI}{2 \pi r} = \mu_{\circ} nI$ (n = no. of turns per unit length of solenoid)	1/2	
	(c) For the loop 1, Ampere's circuital law gives $B_1 \cdot 2\pi r_1 = \mu_0(0)$ i.e. $B_1 = 0$	1/2	
	Thus the magnetic field, in the open space inside the toroid is zero.		

	Also at point Q, we have $B_3(2\pi r_3) = \mu_0(I_{enclosed})$

a) The circuit diagram is shown here

The emitter-base junction, being forward biased, the majority charge carriers (electrons), from the emitter, flow into the base region constituting the emitter current(I_E)

The base region, being very thin, only a (very) small fraction, of these charge carriers, swamps the holes present in the base region resulting in a (small) base current (I_B) .

The majority of these charge carriers, are attracted by the (reverse biased) collector. These make up the collector current (I_C) .

It is clear, therefore, that

$$I_E = I_C + I_B$$

b) The circuit diagram, of a transistor, working as an amplifier, in its CE mode, is shown here.

If a small sinusoidal voltage is superimposed on the dc base bias by connecting the source of this signal in series with V_{BB} supply. Then the base current will have sinusoidal variations superposed on the values I_B . As a consequence the collector current also will have sinusoidal variation superimposed on the value of I_C producing in turn corresponding change in the output voltage V_o .

(i) Let $\frac{d\phi}{dt}$ be the tare of charge of flux through each turn of the primary and the secondary coil

$$\frac{e_1}{e_2} = -N_1 \frac{d\phi}{dt} / -N_2 \frac{d\phi}{dt} = \frac{N_1}{N_2}$$

- c) Main assumptions
 - (i) The primary resistance and current are small
 - (ii) The flux linked with the primary and secondary coils is same / there is no leakage of flux from the core.
 - (iii)Secondary current is small (Any one)

The first refracting surface ABC forms the image I_1 of the object O. The image I_1 acts as a virtual object for the second refracting surface ADC which forms the OJESTIONBAT real image I as shown in the diagram

For refraction at ABC
$$\frac{n_2}{v_1} - \frac{n_1}{u} = \frac{n_2 - n_1}{R_1} - \dots$$
 (i)

For refraction at ADC

$$\frac{n_2}{v} - \frac{n_1}{u} = \frac{n_1 - n_2}{R_{12}}$$
 ----- (ii)

Adding equation (i) and equation (ii)

$$\frac{n_1}{v} - \frac{n_1}{u} = (n_2 - n_1)(\frac{1}{R_1} - \frac{1}{R_2})$$

$$\frac{1}{v} - \frac{1}{u} = (\frac{n_2}{n_1} - 1)(\frac{1}{R_1} - \frac{1}{R_2})$$

We know If
$$u = \infty$$
, $v = f$

$$\frac{1}{v} - \frac{1}{u} = \frac{1}{f}$$

$$\frac{1}{f} = (n_2 - 1)(\frac{1}{R_1} - \frac{1}{R_2})$$

(b)
$$\frac{1}{f} = (\mu - 1) \left(\frac{1}{R_1} - \frac{1}{R_2} \right)$$

 $\frac{1}{20} = (1.55 - 1) \left(\frac{1}{R} - \frac{1}{-R} \right)$
